

Fleet Utilisation & Mileage Analysis

Introduction

The purpose of this analysis on a fleet management company's car inventory is to identify patterns in vehicle mileage, usage and warranty status. The nature of this review is to understand how the fleet is being used and whether management may decide on taking action based on this analysis.

Data Summary

The dataset includes information on the drivers, the make, the model, the age, the miles driven and whether the warranty covers their vehicle. I analysed the data to see which vehicles and drivers were being used the most and whether the cars were at risk of driving beyond their warranty limits.

Key Findings

1. Toyota Camry, being driven over 400,000 miles make up the most driven car in the fleet despite the fact that 83% are aged 12 years or higher which suggests that they are the most relied upon car in the fleet.
2. The fleet consists of a small number of manufacturers with Ford accounting for 14, the largest in the fleet, and Honda in second with 11 cars. This is significant as together, both manufacturers make up more than 50% of the fleet.
3. There are 4 cars that require closer monitoring and maintenance review due to being between 14 to 18 years since its manufacture date and, this is the main reason, 3 cars exceed the warranty limit of 75000 miles and 1 car exceeds 100000 miles driven. This will inevitably lead to a higher risk of repair costs.

Recommendations

To improve management of the fleet, I would recommend to monitor high mileage cars more closely, review whether some drivers are using more cars than others and check cars near or those which exceed their warranty limit for replacement in the future.

Conclusion

The analysis shows that the fleet is running in good conditions however some cars and drivers are responsible for higher usage relative to the others. This results in higher degrees of wear and tear and therefore an increased risk of maintenance costs.
